

A Correction to the Equipartition Theorem by the Lennard-Jones Potential

Sahil Bhalla and Tiane Maestas

Motivation - Gases Are Not Always Ideal

- Ideal Gas: Inter-particle forces are not significant
- Ideal Gas: High-Temperature/Low Density

Ideal Gas

Non-Ideal Gas

Partition Function of Non-Ideal Gas

- Reduces to two partition functions
- U = potential energy
- Z_c , integral over all possible configurations of N particles
- True for all density/temperature

$$Z = \frac{1}{N!} \left(\frac{\sqrt{2\pi m k T}}{h} \right)^{3N} \int d^3 r_1 \cdots d^3 r_N e^{-\beta U_{\text{pot}}}$$
$$= Z_{\text{ideal}} \cdot \frac{1}{V^N} \int d^3 r_1 \cdots d^3 r_N e^{-\beta U_{\text{pot}}},$$

$$Z_c = \frac{1}{V^N} \int d^3 r_1 \cdots d^3 r_N e^{-\beta U_{\text{pot}}},$$

Cluster Expansion

- Rewrite Z_c as diagrammatic perturbation series
- Each diagram represents a cluster of simultaneously interacting molecules
- At low density the second expression is well behaved

$$Z_c = 1 + \begin{array}{c} \bullet \\ | \\ \bullet \end{array} + \begin{array}{c} \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array} + \left(\begin{array}{c} \bullet \\ | \\ \bullet \end{array} \begin{array}{c} \bullet \\ | \\ \bullet \end{array} \right) + \begin{array}{c} \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array} + \begin{array}{c} \bullet \quad \bullet \\ | \quad | \\ \bullet \end{array} + \begin{array}{c} \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \end{array} \\ + \left(\begin{array}{c} \bullet \\ | \\ \bullet \end{array} \begin{array}{c} \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array} \right) + \left(\begin{array}{c} \bullet \\ | \\ \bullet \end{array} \begin{array}{c} \bullet \\ | \\ \bullet \end{array} \begin{array}{c} \bullet \\ | \\ \bullet \end{array} \right) + \dots$$

$$Z_c = \exp \left(\begin{array}{c} \bullet \\ | \\ \bullet \end{array} + \begin{array}{c} \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array} + \begin{array}{c} \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \end{array} + \begin{array}{c} \bullet \quad \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array} + \begin{array}{c} \bullet \quad \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array} + \dots \right).$$

The Lennard-Jones Potential

$$u(r) = u_0 \left[\left(\frac{r_0}{r} \right)^{12} - 2 \left(\frac{r_0}{r} \right)^6 \right].$$

- Basic model for pairwise interactions
- Very repulsive at short distances $\leq r_0$
- Slightly attractive at further distances
- r_0 roughly the diameter of a molecule
- u_0 depth of potential well, or strength of attraction/repulsion

The Lennard-Jones Potential

$$u(r) = u_0 \left[\left(\frac{r_0}{r} \right)^{12} - 2 \left(\frac{r_0}{r} \right)^6 \right].$$

(Potential)

(Force)

Problem

Is there a correction to the ideal gas internal energy when adding pairwise interactions by the Lennard-Jones potential? And if so what is the sign of this correction and how do variables of the simulation affect the significance of this correction?

$$\begin{array}{ll} KE_{avg} = \frac{3}{2} kT & \text{per molecule} \\ KE_{avg} = \frac{3}{2} RT & \text{per mole} \end{array} \quad \begin{array}{l} k = \text{Boltzmann constant} = R/N_A \\ k = 1.38066 \times 10^{-23} \text{ J / K} \\ R = \text{universal gas constant} = kN_A \\ R = 8.3145 \text{ J / mol K} \end{array}$$

Solution

$$\textit{Kinetic Energy} = U_{\text{tot}} + U_{\text{pot}}$$

- At time $t < 0$ the particles are far apart and static. (Non-Interacting)
- At time $t = 0$ the particles are given random initial kinetic energy.
- At time $t > 0$ the particles interact through some negative potential energy.

$t < 0$

$t > 0$

Trial #:	Total Energy:	Potential Energy:	Kinetic Energy:
1	998.4315	-37.31397	1035.745
2	998.8915	-34.51808	1033.41
3	1001.637	-26.3421	1027.979
4	999.1211	-34.13357	1033.254
5	1002.51	-23.43491	1025.945

(Note: each of these values are averages over continuous calculations for 2 seconds)

There is an increase in total kinetic energy!

- This corresponds to only a 3% correction of the kinetic energy.
- However, our simulation can only hold accuracy at low temperature/energy which means that this is a correction of 3% at approximately an initial temperature of 0.00016K.

Higher Energies

At higher energies the correction becomes much less significant! This simulation is at 10x the energy of the first and only has a correction of about 0.04% to the kinetic energy.

Thank you!
